Investment Return & Risk Metrics

Account	Simple Ret.	CAGR	XIRR	TWRR (Ann.)	Volatility	Max DD	DD Duration	Recovery
Vanguard	-14.1%	-36.6%	-47.7%	-38.2%	90.5%	-25.1%	31 days	Not yet
Fidelity	+14.7%	+23.1%	+26.4%	+26.4%	0.9%	0.0%	-	-
Schwab	+19.4%	+31.0%	+40.1%	+46.1%	32.6%	-12.7%	60 days	Not yet
TSP	+4.6%	+6.7%	+12.0%	+12.3%	0.2%	0.0%	-	-

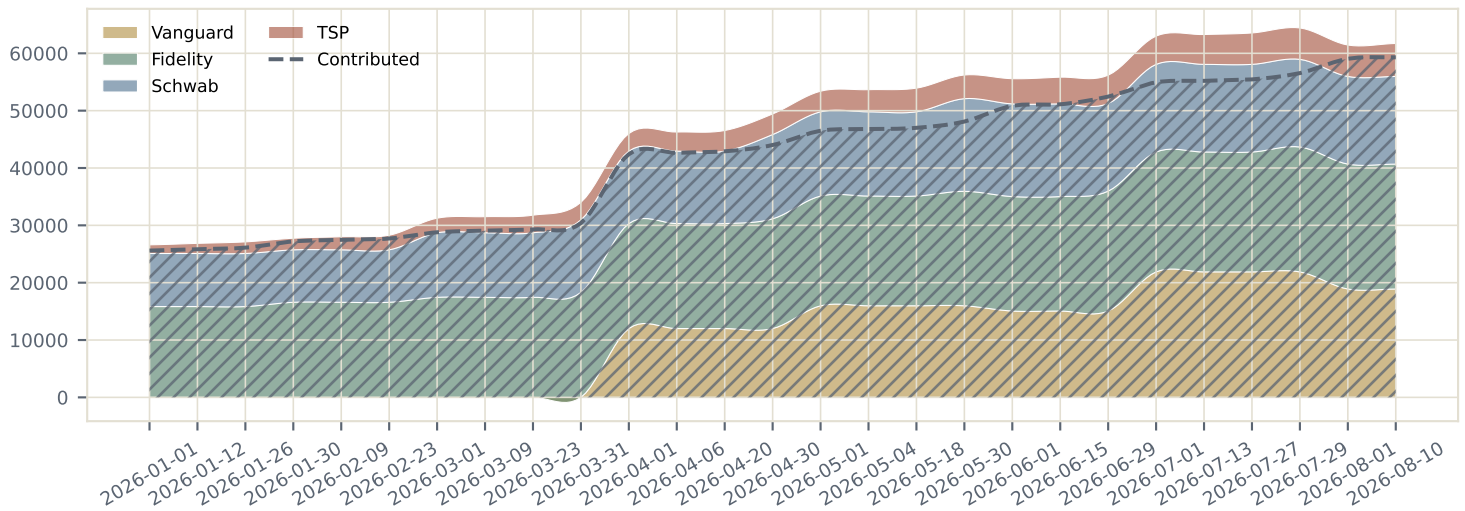

Simple Return, CAGR, and XIRR all describe your money's growth; TWRR isolates the investment's own performance from your deposit timing. Volatility, Max Drawdown, Drawdown Duration, and Recovery Time together describe how bumpy the ride was. See the following pages for a full explanation and the formula behind each.

2026 Federal Bracket Breakdown - Single

Rate	Bracket	Amount Taxed	Tax
10%	\$0.00 – \$12,400.00	\$12,400.00	\$1,240.00
12%	\$12,400.00 – \$50,400.00	\$38,000.00	\$4,560.00
22%	\$50,400.00 – \$105,700.00	\$15,760.00	\$3,467.20

Estimate only, based on 2026 IRS federal tax brackets and the 2026 standard deduction for Single. Doesn't account for credits, itemizing, or income outside what's tracked in this app - not a substitute for a real tax preparer.

Investment Insights

Portfolio (blended across all accounts)

● Timing drag

Poor deposit timing cost you about 9.2 points versus just holding the asset (TWRR +18.4% vs. XIRR +9.2%). The underlying investment is doing better than your own return.

Vanguard

● Timing drag

Poor deposit timing cost you about 9.5 points versus just holding the asset (TWRR -38.2% vs. XIRR -47.7%). The underlying investment is doing better than your own return.

● Slow to recover

A -25.1% drawdown has taken a long time to recover from (still ongoing). Consider whether you're comfortable seeing this account underwater for that long.

Schwab

● Timing drag

Poor deposit timing cost you about 6.1 points versus just holding the asset (TWRR +46.1% vs. XIRR +40.1%). The underlying investment is doing better than your own return.

● Strong risk-adjusted return

A Calmar ratio of 2.44 means the annual return (+31.0%) comfortably outweighs the worst historical drawdown (-12.7%).

Thresholds are banded by each account's Risk Profile (Low/Medium/High) and are heuristics meant to prompt a closer look, not investment advice.

Return Metric Definitions

Simple Return

Growth as a plain percentage of what's been put in: how much more (or less) the account is worth today than the total of every contribution, with no adjustment for how long any of that money has been invested.

$$\text{Simple Return} = (\text{Current Value} - \text{Total Contributed}) / \text{Total Contributed}$$

CAGR (naive)

Annualizes that same growth over the account's elapsed history. It still ignores *when* money went in -- a lump sum from day one and a dozen equal monthly deposits get treated identically -- so it's a rough read, most useful for an account funded mostly by one initial deposit.

$$\text{CAGR} = (\text{Current Value} / \text{Total Contributed})^{(1 / \text{Years})} - 1$$

XIRR

The cash-flow-timed version of CAGR: every contribution is dated individually against the current value, so a deposit made last month isn't credited with a full year of growth the way CAGR would credit it.

$$\sum CF_i / (1 + r)^{((\text{Date}_i - \text{Date}_0) / 365)} = 0 \quad - \text{ solved for } r$$

Time-Weighted Rate of Return (TWRR)

Links together the return from each valuation to the next, backing out any contributions made in between -- so the number reflects how well the money performed, not how much (or when) was added to the account. This is the one that isolates the investment's own performance, independent of your deposit behavior.

$$\text{TWRR} = \prod (1 + r_i) - 1, \quad r_i = (\text{End}_i - \text{Contrib}_i - \text{Start}_i) / \text{Start}_i, \quad \text{annualized over the full history}$$

Risk Metric Definitions

Annualized Volatility

How much an investment's periodic returns swing around their average, scaled up to a yearly figure. Higher means a bumpier ride; lower means steadier, more predictable performance period to period.

$$\sigma(\text{annual}) = \sigma(\text{per period}) \times \sqrt{(\text{periods per year})}$$

Maximum Drawdown, Duration & Recovery Time

These three numbers describe the single worst decline in the account's history together: Max Drawdown is the worst percentage drop from any high point to the low point that followed it, measured on a contribution-adjusted "growth of \$1" index built from the same per-period returns as TWRR -- so a big drop isn't hidden just because new money happened to land around the same time. Duration is how many days it took to fall from that peak to the trough. Recovery Time is how many days after the trough it took to climb back to that same peak level -- shown as "Not yet recovered" if it hasn't happened yet.

$$\text{Max Drawdown} = \min_i [\text{Index}_i \div \max(\text{Index}_0 \dots \text{Index}_i) - 1]$$

$$\text{Duration} = \text{Trough Date} - \text{Peak Date}$$

$$\text{Recovery Time} = \text{Recovery Date} - \text{Trough Date}$$
